TEST EXECUTION REPORT

PR #11 security and testing deliverables reconciled onto the PR #63 implementation baseline

Project	Task Manager Application	**Report date**	13 November 2026
Reconciliation branch	reconcile/pr11-deliverables-on-pr63	**Report revision commit**	5d55574
Implementation baseline	PR #63 (team lead-designated baseline)	**Original deliverables**	PR #11
PR #63 head used	3f9af8e (known fetched head at reconciliation)	**GitHub CI**	Not yet run / result not available

1. Executive summary

This report records the regression verification performed while reconciling the additional authentication/security tests and testing deliverables from PR #11 onto the PR #63 backend and mobile implementation baseline. The PR #63 implementation was retained; the reconciliation did not replace its backend routes, middleware, database configuration, migrations, or package/lock files.

The local automated test runs passed: 59 backend Jest tests across 3 suites and 78 mobile Jest tests across 13 suites. The Postman collection run passed 41 assertions across 23 requests. Mobile TypeScript type checking and linting also passed. GitHub Actions has not yet been run for this reconciliation branch, so no hosted CI success is claimed.

The RTM was updated to record the additional regression evidence and the two tasks found in the GitHub Projects Testing column (#22 and #25). Those issue records had no descriptions or acceptance criteria when reviewed; existing test coverage is documented, but formal issue-level verification remains pending owner clarification.

2. Scope and reconciliation approach

In scope

- Preserve PR #63 as the backend/mobile implementation baseline.
- Retain additional PR #11 authentication and task-security regression tests that were not already covered.
- Retain and expand the Postman API regression collection.
- Update the Requirements Traceability Matrix (RTM) with test evidence and limitations.
- Preserve the existing PostgreSQL-backed CI checks and make the reconciliation branch eligible for the workflow.

Out of scope / safeguards

- No replacement of PR #63 routes, middleware, database configuration, migrations, or dependency manifests.
- No duplicate CI workflow or PostgreSQL job was introduced.
- No claims are made for unexecuted GitHub-hosted CI or requirements lacking sufficient acceptance criteria.

3. Test execution summary

Test area	Execution	Result	Status
Backend Jest	3 test suites	59 passed; 0 failed	**Passed**
Mobile Jest	13 test suites	78 passed; 0 failed	**Passed**
Postman collection	23 requests, 1 iteration	41 assertions passed; 0 failed, 0 skipped, 0 errors	**Passed**

Test area	Execution	Result	Status
Mobile TypeScript	npm run typecheck	Completed successfully	**Passed**
Mobile lint	npm run lint	Completed successfully	**Passed**
GitHub Actions	Hosted workflow	Not run / no result supplied	**Pending**

Combined automated Jest total: 137 tests passed across 16 suites. Postman assertions are reported separately and are not included in the Jest test total.

4. Backend regression coverage

The backend test suite completed with 59 passing tests across 3 suites. The reconciliation added or strengthened the following coverage:

• Login rejects requests with a missing email or missing password (HTTP 400, validation error).
• Logout rejects requests without an authentication token (HTTP 401, SESSION_EXPIRED).
• Unauthenticated task creation, editing, completion, and deletion are rejected (HTTP 401, SESSION_EXPIRED).
• Session-expiry test setup verifies that the intended session row was updated before asserting expiry behavior.
• The password-change test timeout was increased to accommodate the bcrypt operation under the test environment.

Existing session coverage also exercises logout invalidation, idle expiry at the 30-minute threshold, activity refresh within the allowed window, and SESSION_EXPIRED responses. No additional session-expiry scenarios were added pending coordination to avoid duplication with the mobile session/navigation coverage.

5. Mobile regression verification

The mobile Jest suite completed with 78 passing tests across 13 suites. The suite includes registration validation, login and logout behavior, protected navigation, task screens and task presentation, profile behavior, password changes, and handling of expired sessions.

The session-related coverage includes redirecting away from protected screens after API expiry, expiring stale stored sessions after app restart, handling concurrent expired requests once, and preserving a newer session when an older request expires late. TypeScript type checking and linting both completed successfully.

6. Postman API regression collection

The updated Postman collection is located at **postman/Task_Manager_Backend_Postman_Collection.json**. It uses the Postman v2.1 collection format and contains 23 requests with 41 assertions. The recorded run completed one iteration with 41/41 assertions passing, zero failures, zero skipped assertions, and zero errors.

The collection is organized into Health, Authentication, Tasks, and Security checks. It includes missing-email login, logout without a token, unauthenticated task mutation checks, and authenticated task operations. Requests that depend on authentication require the login step to run first; authenticated logout is run last.

7. Requirements traceability and project-board review

The RTM at **docs/rtm/RTM.md** retains 37 requirement rows (FR-01 to FR-28 and NFR-01 to NFR-09). It records the additional login, logout, and unauthenticated task-operation regression evidence. Additional test-case identifiers remain provisional pending mapping to the approved STP v1.0.

The GitHub Projects Sprint Board was reviewed with the current-iteration filter cleared. Two cards were visible in the Testing column:

Issue	Task	Existing test evidence	Verification status
#22	Email format validation	Backend registration tests cover missing, malformed, and non-string email values; mobile tests cover valid and malformed email inputs.	Existing coverage identified; issue acceptance criteria unavailable.

Issue	Task	Existing test evidence	Verification status
#25	Password strength enforcement	Backend and mobile tests cover minimum length and missing uppercase, lowercase, digit, and special-character requirements.	Existing coverage identified; issue acceptance criteria unavailable.

Both tasks have existing implementation and automated regression coverage in the PR #63 baseline. No duplicate tests were added. Because the GitHub issues had no descriptions or acceptance criteria at review time, this report does not mark either issue formally verified. Issue owners must clarify the acceptance criteria before formal sign-off.

Other RTM limitations retained from the source matrix include missing persistence assertions for valid due dates (FR-12), descriptions (FR-15), priority updates (FR-18), and valid category assignment (FR-19). Issues #20, #50, #51, and #57 also have acceptance-criteria limitations noted in the RTM.

8. CI and environment notes

The existing workflow retains its PostgreSQL-backed backend job, migration checks, database connection/table checks, and mobile verification job. The reconciliation branch pattern was added to the push trigger. The mobile Jest command in CI uses a 15-second test timeout to accommodate the slower rendering test observed in the local environment.

Important: the workflow changes were committed locally, but a GitHub Actions run for this branch has not been confirmed. Therefore, CI is pending and must be checked after the branch is pushed / a pull request is opened.

During mobile dependency installation, npm reported 34 dependency vulnerabilities (1 low, 30 moderate, 3 high). No automatic audit fix or dependency upgrade was applied as part of this reconciliation. Review these findings separately before release.

9. Outstanding items and limitations

1. Run the GitHub Actions workflow on the reconciliation branch and record the actual result and run URL.
2. Coordinate with Shrunga and the team lead on any remaining API/database changes and session-expiry scenarios to avoid duplicate coverage.
3. Obtain acceptance criteria from the owners of issues #22 and #25 before marking them formally verified.
4. Map provisional test IDs to the approved STP v1.0.
5. Consider adding assertions for valid due-date persistence, description persistence, priority update, and valid category assignment.
6. Review the 34 npm dependency audit findings and decide on safe, separately tested remediation.

10. Conclusion

The reconciliation branch contains the PR #63 implementation baseline plus additional PR #11 security regression coverage, an expanded Postman collection, RTM updates, and a workflow update. Local verification passed for backend Jest, mobile Jest, Postman assertions, mobile TypeScript, and mobile lint. Formal sign-off remains subject to hosted CI execution, acceptance-criteria clarification for the Testing-column issues, and resolution or explicit acceptance of the documented traceability gaps.

Evidence and reproducibility

Repository branch: reconcile/pr11-deliverables-on-pr63
Report/RTM commit: 5d55574
Known PR #63 fetched head at reconciliation: 3f9af8e
Postman collection: postman/Task_Manager_Backend_Postman_Collection.json
RTM: docs/rtm/RTM.md
CI workflow: .github/workflows/ci.yml
Backend tests: backend/tests/
Mobile tests: mobile/src/**/__tests__ and service test directories

This report reflects the test outputs and repository state supplied during reconciliation. It does not claim that unexecuted tests, hosted CI, or issue-specific acceptance criteria have passed.
